A tour of the Console

The latest version is at anantharajuc.github.io/QueryAPIGate-website/Guide.dc.html?d=SCREENSHOTS. This copy was made on 4 November 2026.

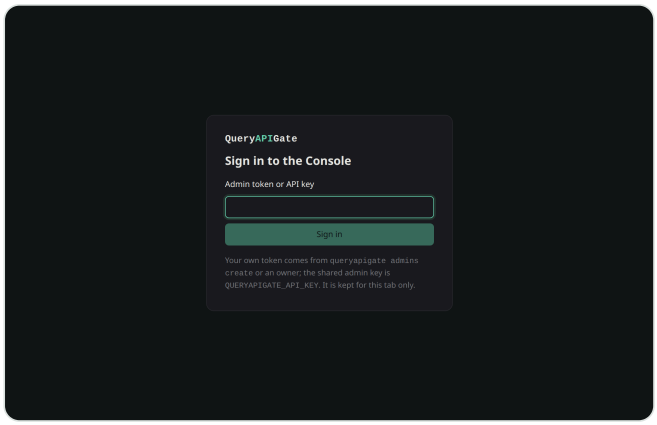

The Console is at `/console` on every QueryAPIGate server - nothing separate to install. Each screen below, with what it's for; click one for the full size. The README has the SQL editor, the demo video and the architecture.

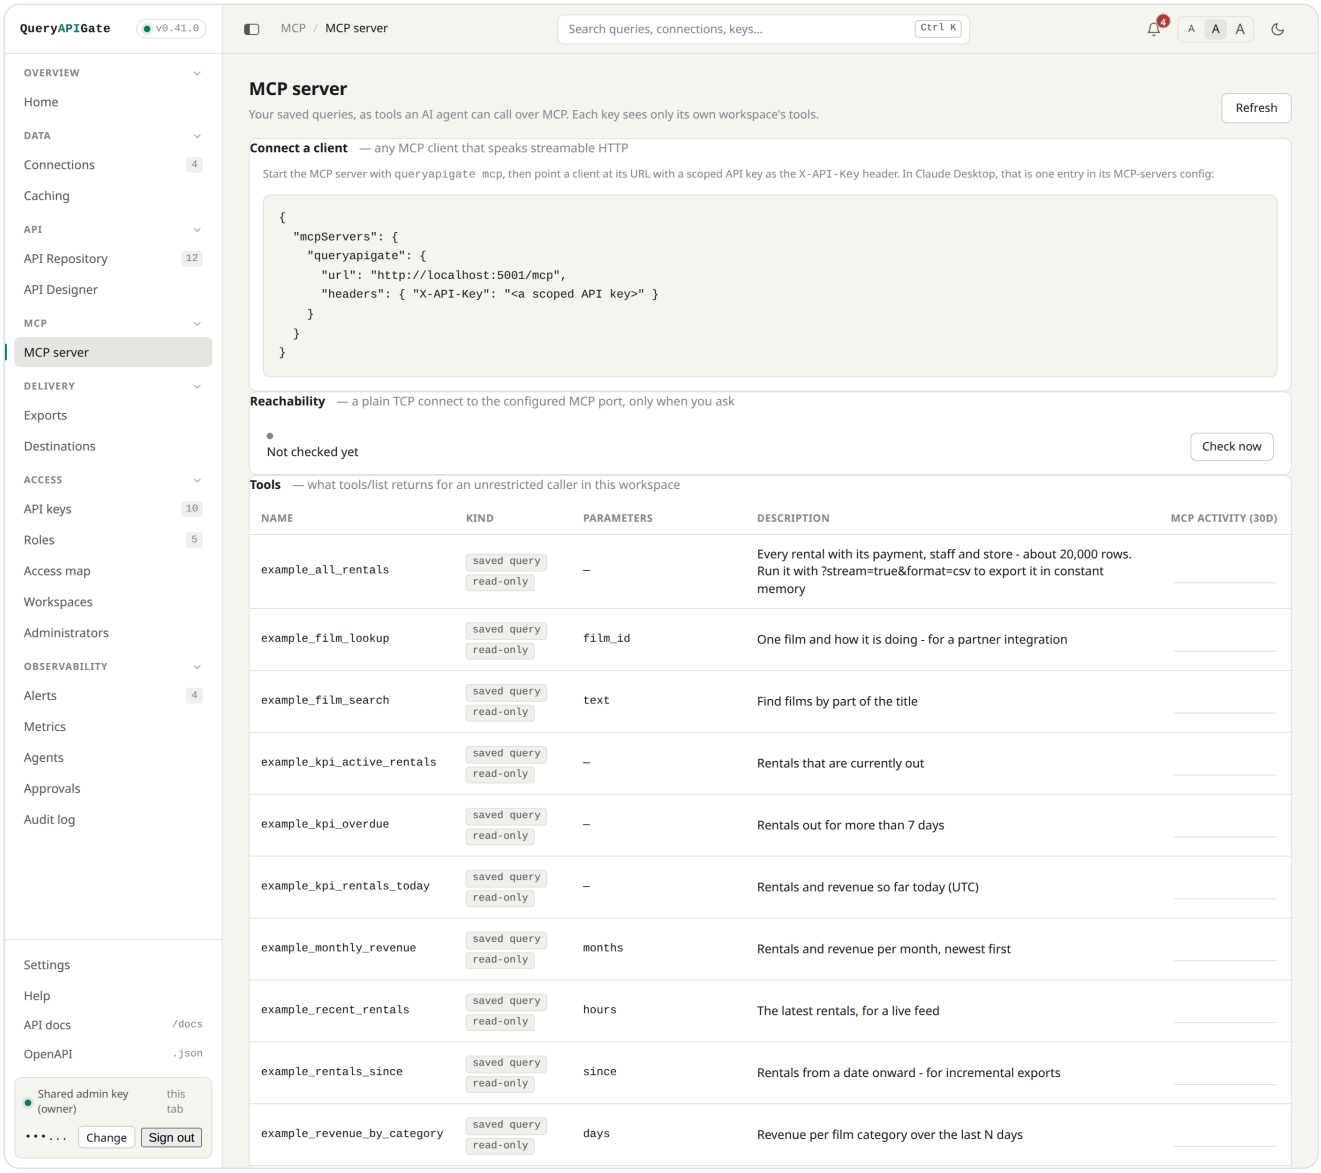

Home: live totals, what needs attention, recent activity, and every recent request - saved APIs and ad-hoc SQL alike.

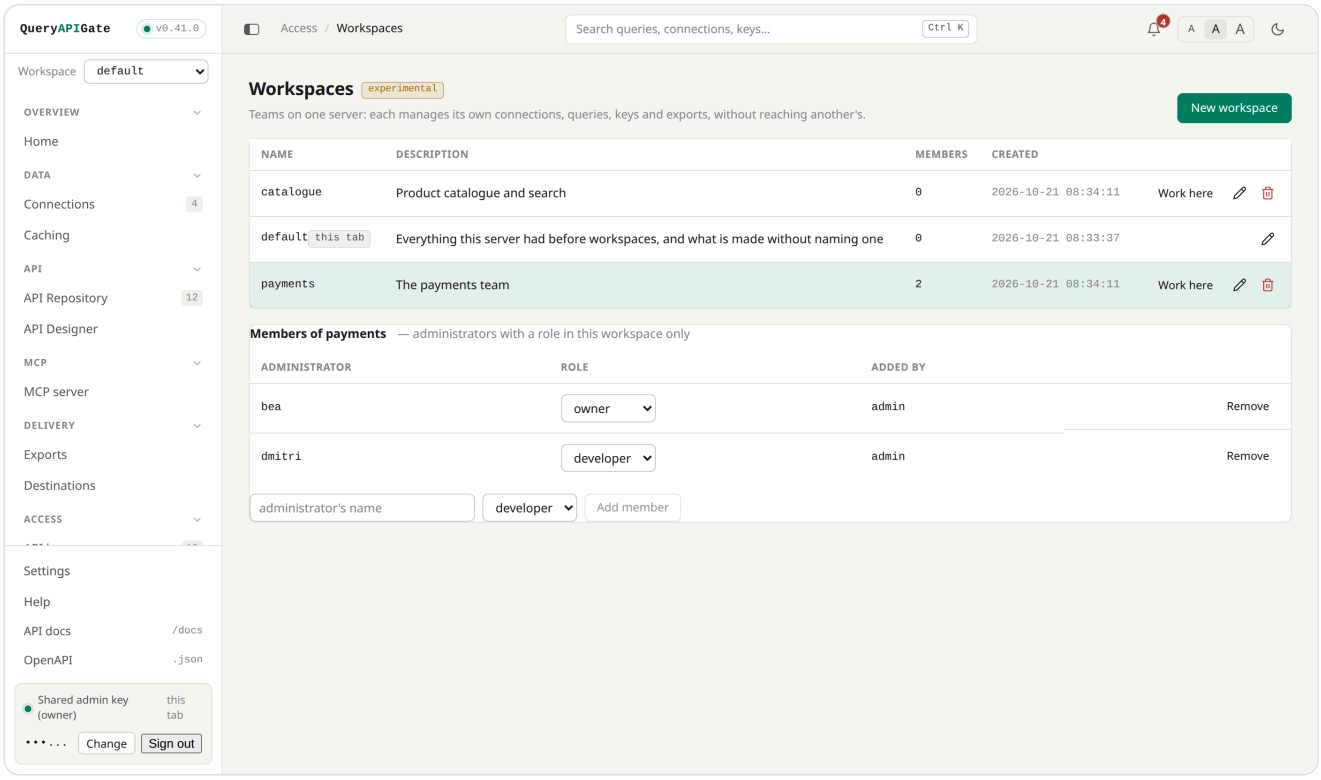

Signed out, a tab sees only the sign-in page - Sign in with SSO when it's set up, or an admin token

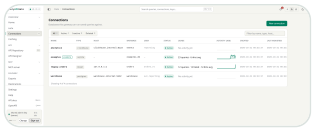

The same page in the dark theme, following the operating system's

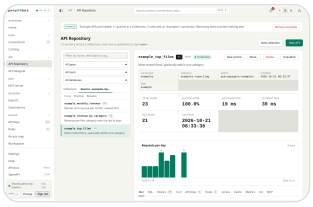

MCP server: your saved queries as governed tools for AI agents - read-only by default, with the connect snippet and a reachability check, the same identity, masking and audit as every other caller.

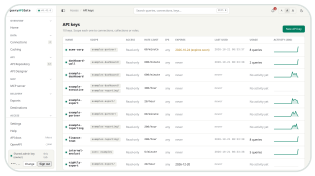

Workspaces (experimental): teams on one server, each running its own connections, queries and keys - with the switcher under the wordmark, and each workspace's members.

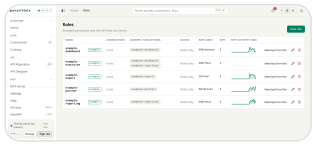

Manage connections across every supported database, with live usage per connection

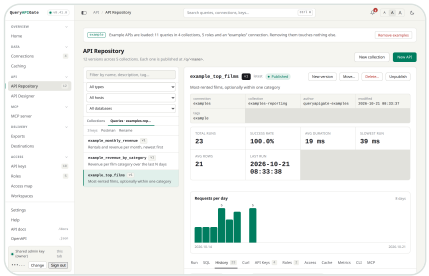

Every saved query becomes a documented REST endpoint - grouped into collections

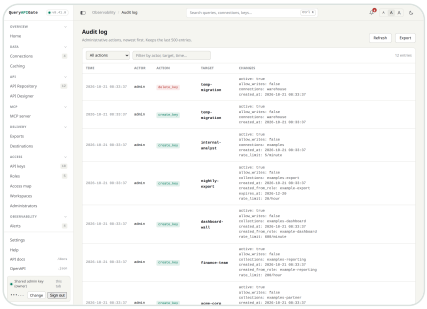

Per-key permissions: connections, specific saved queries, expiry, rate limits - and what each key has actually done

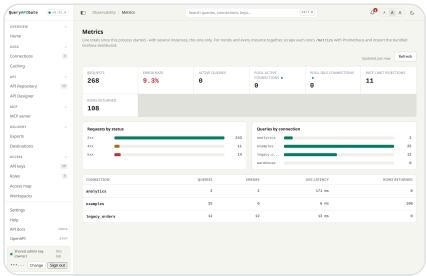

Named roles: a reusable grant template, copied onto a key once at creation

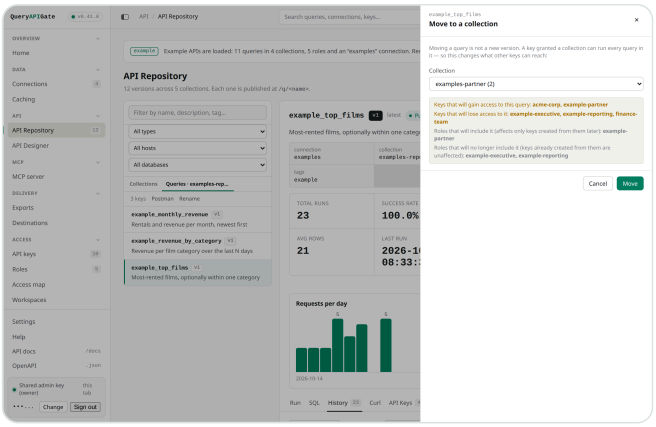

Run history per saved query: who called it, how long it took, and the request ID to find it in the logs

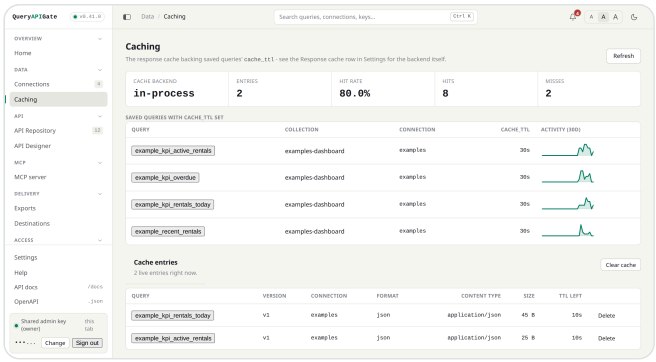

A durable audit log of every configuration change, filterable by action, actor and target

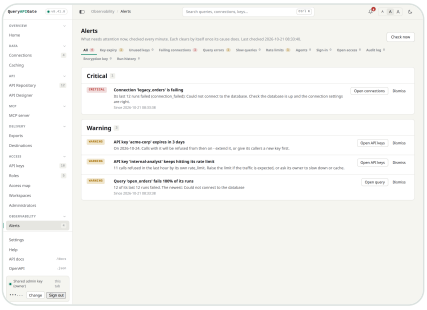

Live metrics with no Prometheus required - or import the bundled Grafana dashboard for history

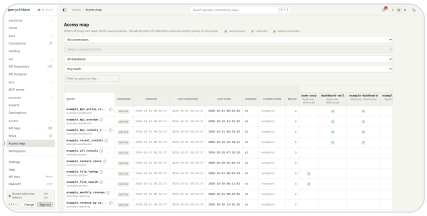

Collections: grant a key a whole group of queries - and see exactly which keys gain or lose access before a query moves

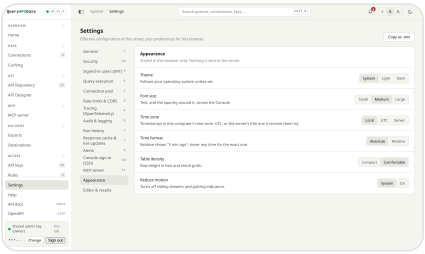

Caching: live hit rate for the response cache backing every saved query's `cache_ttl`

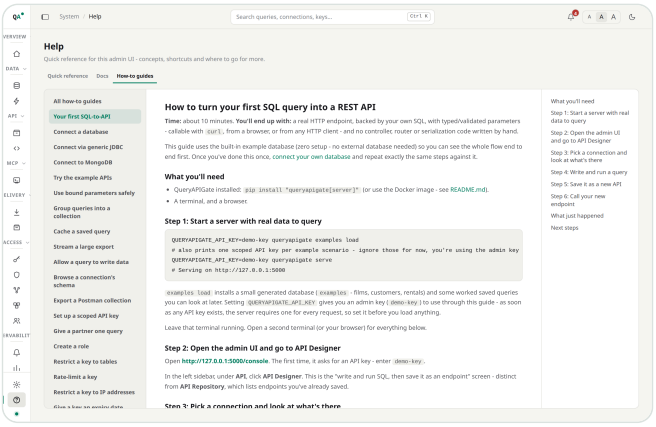

Alerts: failing connections, expiring keys, failing or slow queries, rate limits being hit - each with what to do, clearing by itself once fixed

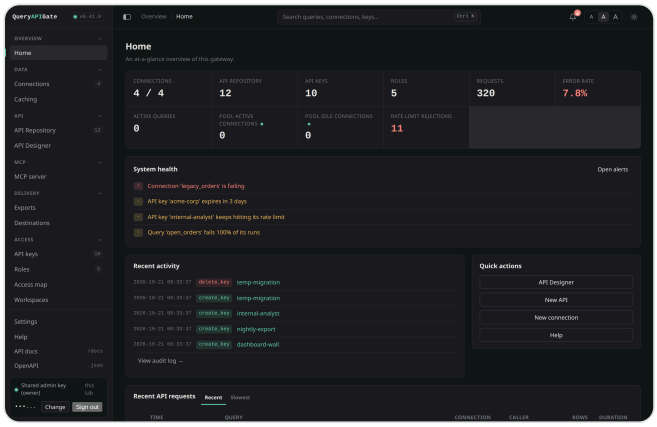

Access map: which key can call which query, and why - one grid instead of reading every grant

Settings: the server's effective configuration, read-only, plus per-browser appearance and editor preferences

Help: the docs and how-to guides for the version you run, inside the Console
